Title: Application Virtualization Comparison Chart

Published on: Virtualfuture.info

Version: 3.0

Document date: September 1st 2009

Authors: Sven Huisman & Matthijs Haverink

Introduction

You might know the previously released VirtualFuture.info Application Virtualization Comparison Charts from 2008. This comparison chart is an updated version of the Chart released September last year and provides an objective overview of features of the major Application Virtualization solutions. Some of the major advantages of Application Virtualization are:

- Migrate to new operating systems without upgrading or replacing legacy applications.
- Lock down corporate endpoints by running applications in user mode without locking out users.
- Minimize application conflicts and regression testing.
- Replicate your virtualized applications like any other enterprise data to maintain an instant-on fail-over plan for your applications.

The following is updated in this chart:

- InstallFree Bridge is now version 1.9.2.6
- Microsoft App-V4.5 added Cumulative Update 1
- Symantec AppStream & SVS Pro are now called EndPoint Virtualizatoin Suite
- ThinApp had a minor update from version 4.0 to version 4.03
- XenoCode Virtual Application Studio had a major upgrade from v2008 to v2009 SP1.

Also new is that we have tested the following products on start-up performance:

- Microsoft Office 2007 Suite (Word)
- Adobe Acrobat Reader
- Mozilla Firefox
- Microsoft Visio
- WinRar

What is Application virtualization

All Application virtualization software vendors have their own definition of Application virtualization. Basically it comes down to this:

Application virtualization enables the deployment of software without modifying the local operating system or file system. It allows software to be delivered and updated in an isolated environment ensuring the integrity of the operating system and all applications. Application conflicts – and the need for regression testing - are significantly reduced. A single application can be bundled and deployed to multiple operating system versions. Applications are easier to provision, deploy, upgrade, and rollback. (VMware's definition).

Methods

In our opinion there are 2 methods to application virtualization:

Standalone:

Applications are encapsulated in a single executable. These executables can run instantly from USB, CDROM or local disk. The applications can also be deployed using a management tool like Microsoft SMS. No agent is required to run the virtualized application.

Centrally controlled access:

Virtualized applications are "distributed" through a central deployment tool. A locally installed agent is required. The applications can be deployed (executables are copied locally) or shortcuts to the applications (located on a network-share) can be presented.

Some products have the capability to create standalone executables, some are only capable to provide application virtualization through an agent installed on the client. There are also products which can do both, but not always simultaneously. For example: with Installfree you can create standalone executables, but if you want to centrally control the distribution of the applications, you have to create a different type of Installfree package.

With both methods streaming is possible. Some products have the streaming feature and others have not. Streaming is when you start a virtualized application located on the network or webserver, only the blocks needed to run the application are copied to a local drive (cache). When more features of the application are used, more blocks are copied to the local cache. Streaming can be available for standalone virtualized applications accessed from the network or when the virtualized applications are presented with a locally installed agent.

Comparison

This comparison chart compares the features of the, <u>in our eyes</u>, <u>most competitive</u> application virtualization products. This might help you select a product that fits your needs. We advice to test the products yourself in a proof of concept before making a definitive choice.

Products that were considered, but did not make it into the chart:

- Ceedo
- Edeavors Technologies Application JukeBox
- LanDesk Application Virtualization
- RingCube MojoPac
- Trigence AE
- Trustware BufferZone
- Novell Zenworks Application Virtualization (OEM-ed from Xenocode)

Versions of products used:

Symantec: Software Virtualization Solution 6.1

Workspace Streaming 6.1

Microsoft: Application Virtualization 4.5 CU1

Citrix: XenApp 5.0 & Streaming Profiler 1.3.1

InstallFree: Bridge 1.9.2.6

VMware: ThinApp 4.0.3 (Build 3313)

XenoCode: Virtual Application Studio 2009 SP1

Thank you

Thank you for reading this comparison and please let us know by e-mail or as a comment on our blog what you think about this chart. We're eager to learn more about the apps so please correct us if you find any errors or when you have suggestions on what's missing in the chart.

The next update of the chart will probably be done when the majority of these vendors have updated their products to support Windows 7.

Kind regards, Sven Huisman & Matthijs Haverink

Application virtualization performance

One of the most important things when it comes to migrating to virtualized applications is user-acceptance. And when users are used to applications that have a startup time of less than 2 seconds, they will not accept the fact that applications startup slower. We decided to measure the launch-time of 5 commonly used applications when virtualized with 6 application virtualization products. We tested the first launch-time of the applications and the second launch-time. The second time the application virtualization product already cached the application (or some of the blocks) on disk or in memory. This is to see the difference in launch-time of cached and non-cached applications. If there is a big difference in launch-time, you can always decide to pre-cache or pre-load the application (if possible) or not virtualize the application at all.

As a result of these tests we can say that no virtualized application has a faster launch-time than when locally installed. This is one of the disadvantages of application virtualization.

The tests we performed were all under the same circumstances. We don't say that you get the same results in your environment but the results are to compare the application virtualization products with each other.

The 5 applications that were tested:

- Microsoft Office Word 2007 (as part of a full featured Office Enterprise suite package)
- Acrobat Reader 9.1
- Firefox 3.5.2
- Microsoft Visio Professional 2007
- Winrar 3.80

Here are the results for the 5 applications. The launch times are in seconds.

Side Notes & Future features

Citrix hasn't released much new stuff the last months, but in February this year they released the XenApp 5 Feature Pack which has:

- ✓ Application Streaming available for all (now also XenApp Advanced Edition) customers
- ✓ Off-line access to virtualized apps, no matter which XenApp version you have.
- ✓ Off-line support added for Single Sign-on.
- ✓ Runs from USB functionality. It needs to be said that this works only if NFTS-formatted. This is because the RADECache needs to be stored on it and run from it. Not commonly used so we marked it as Yes* in the chart.

When you are really using Citrix XenApp as an application virtualization solution you have to take the XenApp Feature Pack. As an application virtualization solution itself Citrix doesn't have to most revolutionary product but when you already have a Citrix XenApp farm running you have to seriously consider using their solution.

InstallFree is one of the newest players on the market with their Bridge and Mini-Bridge products. InstallFree is already ahead of current competition with features like:

- ✓ A self-provisioning portal for users
- ✓ Out-of-the-box Shell Integration
- ✓ Easy AD based Management and Deployment interface
- ✓ Downloading complete virtualized applications from vendor, from within management interface.
- ✓ And last but not least the fact that no clean PC is required for snapshotting/packaging!
- ✓ Host Interconnectivity policies: use ADM files to control how virtual app connects to host OS
- ✓ Application policies : use original ADM files to control virtualized apps.

InstallFree had a focus on more and more new features which made their product the most innovative of the bunch. However they had some stability issues. In their last release hardly any new feature has been added and a lot of effort has gone into stabilizing the product. In the upcoming release InstallFree adds Windows 7 and 64-bit environments support.

We also know that InstallFree at this moment is working on their Desktop product which is a completely virtualized desktop environment without using any VM/VDI technology and therefore does not require any changes to your existing infrastructure.

Microsoft has released App-V 4.5 (formerly known as Softgrid) already a year ago. Since then only a service pack was released. The upcoming version 4.6 is currently in beta and will be one of the first to be able to

virtualize 64-bits applications. What needs to be said about App-V is that the desktop client is currently only available when you have bought SA (Software Assurance). Only then it then can be obtained by purchasing the MDOP (Microsoft Desktop Optimization Pack). A couple of the features in 4.5 are:

- ✓ HTTP streaming.
 - App-V 4.5 will support streaming virtual applications from an IIS server (version 6 or 7).
- ✓ Dynamic Suite Composition (DSC).
 - DSC allows the flexibility to control virtual application interaction.
- ✓ Create MSI packages
 - The ability to create MSI packages directly from the Sequencer.
- ✓ Improved integration with SCCM 2007 R2.
- ✓ The ability to deploy virtual applications via SCCM will be seamless for SCCM administrators.
- ✓ HTTP streaming

 Virtual applications can be streamed via HTTP.
- ✓ Reporting.
 - Application usage information is now recorded locally on each client and then sent to an App-V Management Server during Publishing Refresh. This means that offline usage of applications or usage of applications when streaming from different sources is now all accounted for properly in the App-V database.
- ✓ New MSI package capability.
 The ability to publish and stream MSI packages.
- ✓ Standalone mode.

The virtualized applications are packaged in an .MSI file and can be distributed via the same mechanism as the installed applications.

The Symantec product line concerning the application delivery space is still a bit unclear. In the past, Symantec acquired the Altiris SVS solution and the AppStream solution. The latest release of both products is now version 6.1. You can still use these 2 applications separately, but combined together you

are able to stream virtualized applications. The downside is that you first have to create a SVS-package, export it and then convert it to a stream. Besides that, you lose some functionality when you decide to stream the virtualized application and when the applications are not pre-loaded, streaming the virtualized packages can be very slow. You can still use the included Notification Server-based Software or the Altiris Deployment Solution to distribute (not stream) you virtualized applications. In the chart the base is to stream virtualized applications.

Side note for the chart:

Application Interconnectivity / Binding: Yes, but this is questionable. When creating virtual layers as Symantec call them, you have the option of isolating a layer. When selected, there is no interconnectivity and when not selected there is. But then again, when the applications are not isolated, conflict can still occur.

Safe as MSI: Yes, but not when using streaming capabilities.

Running virtualized applications from CD-ROM and USB: Yes, but only with a client locally installed. How it works is that the cache is placed in a self extracting executable on the device so that it can be launched from there using the locally installed client.

VMware's ThinApp has had a "major" update in June 2008. The biggest update was more the name-change (VMware acquired Thinstall in 2008) than a real product update. Ever since, VMware only released minor updates. The latest is 4.0.3.

VMware does not release roadmap info or future feature insights for publish or print. It is only available directly to partners, customers and sales prospects by trained VMware representatives and under non-disclosure agreement. However, during VMworld 2009 there is a session about ThinApp regarding upcoming features:

- ✓ The management SDK
- ✓ Batch MSI conversion using WIX and Workstation
- ✓ VMware View integrations
- ✓ Application compatibility detection engine

One note on the chart: ThinApp is not capable of streaming applications from HTTP(s) but it is capable of getting updates from a HTTP(s) source.

XenoCode has just recently (and secretly) released their Service Pack1 for Virtual Application Studio 2009, this is 6 months after the release of VAS 2009, in February. The major improvements since the 2008 version are:

- ✓ AD Deployment and embedded security
- ✓ Windows Shell integration
- ✓ Enhanced sandbox management (more control over app-linking and communication)
- ✓ One-click MSI import
- ✓ Improved dynamic application linking (interconnectivity)
- ✓ New application templates

In the previous chart we had the interconnectivity part set to no because XenoCode wasn't really connecting bubbles (you had to repackage every package). Now they've changed that and that does make XenoCode VAS 2009 SP1 a more mature product. We do have to say that XenoCode doesn't seem to be keen on spreading information about their products. SP1 for VAS2009 had been released without any announcement and release notes are hard/not to find.
